GENERATION OF THE ENOLATE OF ACETALDEHYDE FROM NON-CARBONYL SUBSTANCES AND ITS C-ALKYLATION, O-ACYLATION AND O-SILYLATION

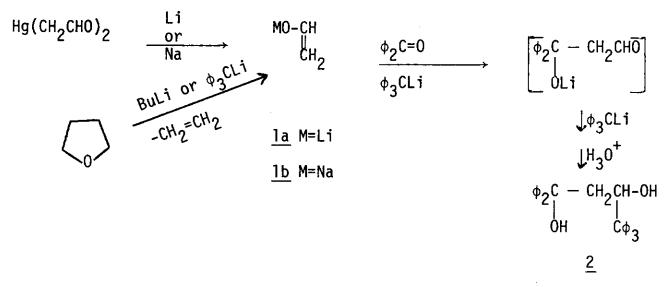

Michael E. Jung ^{*} and Roberto B. Blum

Contribution No. 3882 from the Department of Chemistry, University of California, Los Angeles, California 90024 (Received in USA 8 August 1977; received in UK for publication 7 September 1977)

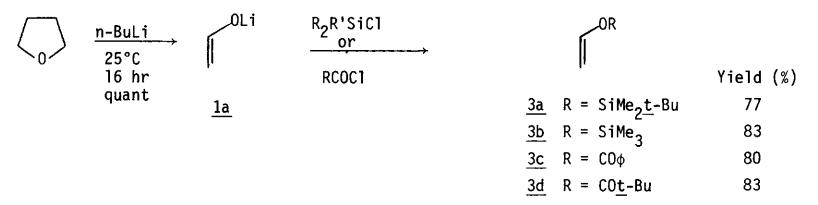

Reaction of the enolates of ketones and aldehydes with a variety of substrates (alkyl and acyl halides, α , β -unsaturated carbonyl compounds, Mannich bases, trialkylsilyl halides, and other compounds) has long been a cornerstone of synthetic organic chemistry.¹ However, this extensive store of reactions cannot be utilized with the enolates of reactive aldehydes (in particular acetaldehyde the simplest carbonyl compound having α -protons) due to facile base-catalyzed polymerization of the starting material and/or products. For these reasons, various indirect methods have been developed for the alkylation of aldehydes, e.g., enamines² and imine anions.³ However, these techniques have never been successfully extended to the alkylation of acetaldehyde. We report now a solution to the theoretical problem, namely experiments which have resulted in improved procedures for the generative of the lithium enolate of acetaldehyde and its 0-acylation and 0-silylation and a new technique for the C-alkylation of acetaldehyde via its tributyltin enolate.

Several years ago, Nesmeyanov and co-workers prepared the lithium and sodium enolates of aceta dehyde <u>lab</u> by reduction of the readily available α -mercurio aldehyde with the respective alkali metals.⁴ However, these workers claimed that these compounds <u>lab</u> were incapable of clean reaction with various substrates including alkyl and acyl halides.⁴ Later, Bates⁵ showed that the lithium enolate of acetaldehyde <u>la</u> could be formed from treatment of tetrahydrofuran (THF) with n-butyllithium, ethylene being the only other by-product. However, no study of the reactivity of <u>la</u> was undertaken. Finally Tomboullian and co-workers reported the generation of <u>la</u> from THF by treatment with excess n-butyllithium and trityl lithium and its <u>in situ</u> trapping with benzophenone to afford the pentaphenyl diol <u>2</u>.⁶

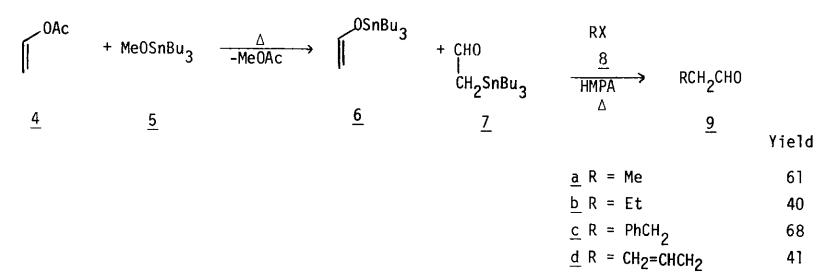

3791

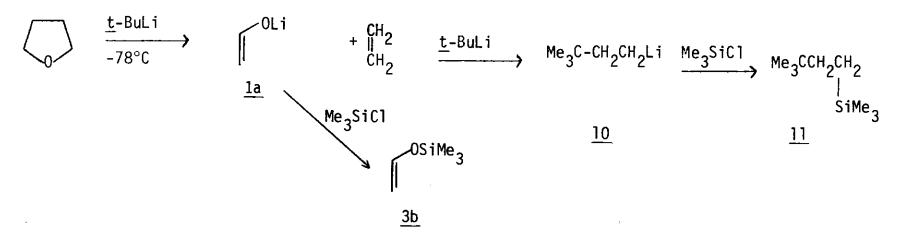

We have found that reaction of n-butyllithium with THF at 25°C for 16 hr under a nitrogen atmosphere affords the desired lithium enolate of acetaldehyde <u>la</u> in essentially quantitative yield based on the alkyllithium. Silylation and O-acylation of this enolate could be easily accomplished. Addition of <u>tert</u>-butyldimethylsilyl chloride afforded the silyl enol ether <u>3a</u> in excellent yield. Due to the small difference in boiling points between THF and trimethylvinyloxysilane <u>3b</u>, it was more convenient to remove all of the THF from the solution of the enolate <u>la</u>, add diglyme and then the silyl chloride, to afford after workup a good yield of the silyl enol ether <u>3b</u>. In order to effect O-acylation, it was necessary to add a solution of the enolate <u>la</u> in THF to 3 equiv. of benzc chloride or pivaloyl chloride at 25°C in 1:1 THF hexamethylphosporic triamide (HMPA) followed by stirring for 5 hr, which furnished excellent yields of the enol esters <u>3cd</u>.

Attempted C-alkylation of the lithium enolate <u>la</u> afforded mainly polymeric material under nearl all experimental conditions. However by the use of the tributyltin enolate <u>6</u> (and its C-stannylatec isomer <u>7</u>), C-alkylation could be successfully accomplished.⁷ Pereyre, Valade, and co-workers have reported that <u>6</u> could not be prepared by the usual procedure of reacting vinyl acetate <u>4</u> with methoxytributylstannane <u>5</u>,⁸ echoing similar statements of Nesmeyanov and his associates.⁹ However 10 we have found that under carefully controlled conditions one can prepare a 2.5:1 mixture of tributylvinyloxystannane <u>6</u> and α -tributylstannylacetaldehyde <u>7</u> in quantitative yield from <u>4</u> and <u>5</u>.¹¹ Heating a solution of <u>6</u> and <u>7</u> with an alkyl halide <u>8a-d</u> in HMPA in a sealed tube at 110°C (75°C for <u>8a</u>) for 10 min (for <u>8ab</u>), 30 min (for <u>8d</u>) or 1 hr (for <u>8c</u>) affords fair to good yields of the C-alkylation products <u>9a-d</u>.¹² Thus this method permits the C-alkylation of the simplest carbonyl compound with α -protons.

In addition to trapping the lithium enolate of acetaldehyde from the decomposition of THF with alkyllithium, we have also successfully trapped the ethylene by-product. When a solution of excess trimethylchlorosilane in THF was treated at -78° C with 2 eq of <u>tert</u>-butyllithium, several products were obtained, two of which were clearly identified (NMR, IR, MS) as the silyl enol ether <u>3b</u> and trimethyl 4,4-dimethylbutylsilane <u>11</u>.¹³ Thus the ethylene generated from the THF was trapped by <u>tert</u>-butyllithium to give the primary anion <u>10</u> which was then silylated. This is the first example of the trapping of ethylene from THF.

The techniques described herein should now allow synthetic chemists to use acetaldehyde in a large variety of alkylation and acylation reactions.

- 10. A solution of the methoxystannane 5 in excess vinyl acetate 4 is stirred under reduced pressure at 25°C to remove methyl acetate as it is formed. When the removal of methyl acetate is comple the excess vinyl acetate is evaporated at 25°C under reduced pressure to leave a mixture of 6and 7. It is absolutely necessary that the reagents are scrupulously dried and that the reactio be carried out under an inert atmosphere. Compounds 6 and 7 could not be formed cleanly by the trapping of the lithium enolate <u>la</u> with tributyltin chloride.
