Efficient Total Synthesis of Racemic and Optically Active Cyclobut-A and Simple Analogues†

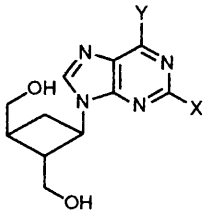
Michael E. Jung* and Adam W. Sledeski

Department of Chemistry and Biochemistry, University of California, Los Angeles, California 90024, USA

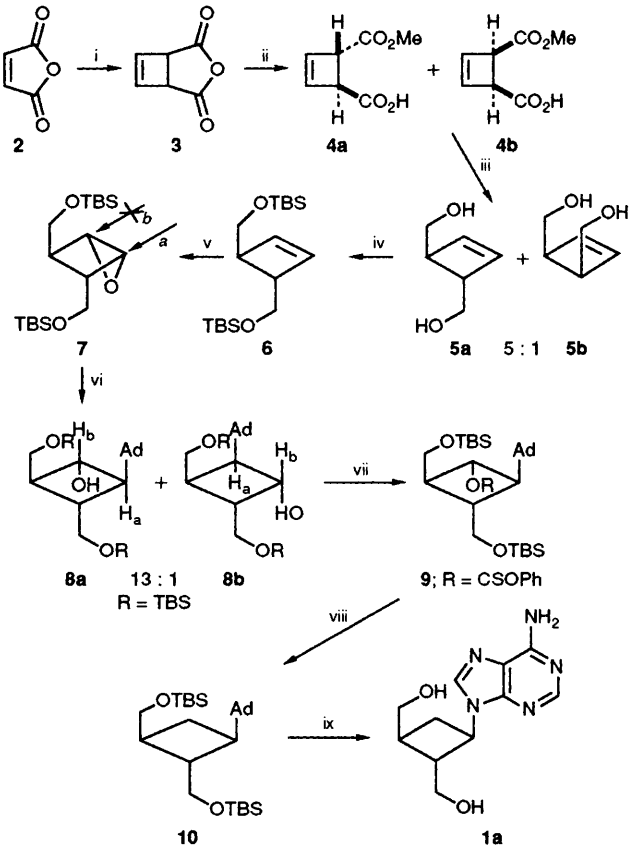
Rapid synthesis of the potent antiviral agent, cyclobut-A, **1a**, from the inexpensive starting materials maleic anhydride and acetylene, in both racemic and optically active forms, is described; the route also allows for the preparation of several hydroxylated and keto analogues in good overall yield.

In 1989 Honjo and coworkers[1] prepared the unnatural products, cyclobut-A and cyclobut-G, **1a**, **b**, carbocyclic analogues of the known antiviral agent oxetanocin A,[2] and demonstrated that they were strongly antiviral.[1] Since then these compounds have been prepared by a number of different routes[3] and have been shown to exhibit very high activity against HIV infections.[4] We report here a new, very efficient synthesis which affords cyclobut-A **1a** in 20% overall yield from the inexpensive, readily available anhydride **3** and permits the preparation of novel analogues of cyclobut-A, namely the alcohols **11** and **13** and the ketone **14**.

Photocycloaddition of acetylene to maleic anhydride **2** has been carried out by several groups and proceeds in good yield (69–72%) to give the anhydride **3** (Scheme 1).[5] Treatment of **3** with sodium methoxide in methanol effected both methanolysis and epimerization to afford a mixture of the *trans* and *cis* monoesters **4** in which the *trans* isomer greatly predominated (~5 : 1).‡ This mixture was not purified but rather directly



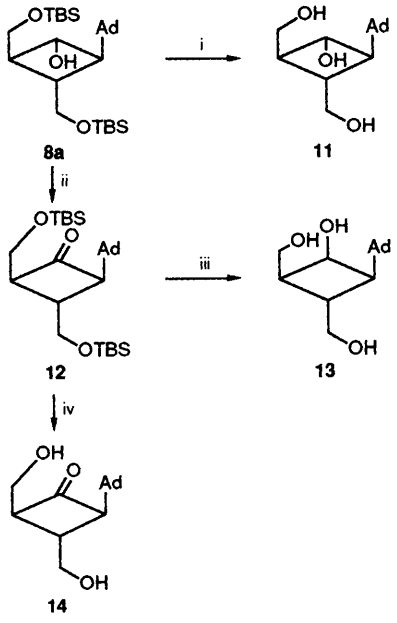
1a; X = H, Y = NH_2
1b; X = NH_2, Y = OH



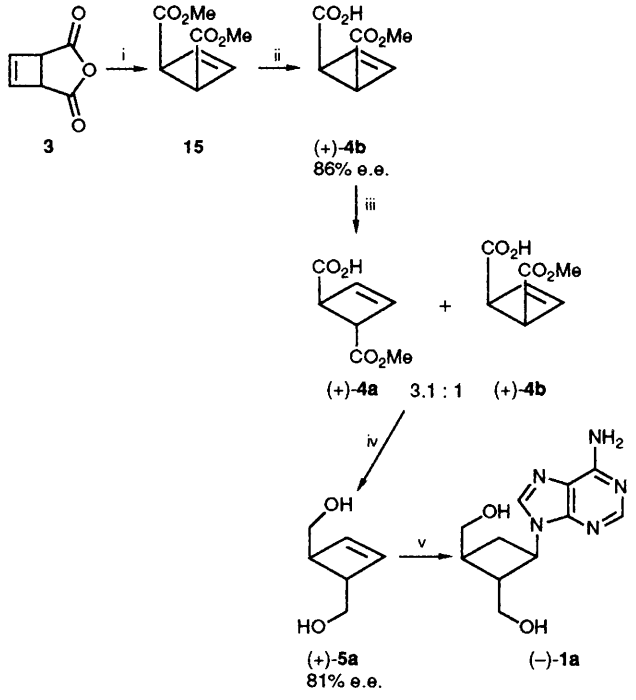
Scheme 1 *Reagents and conditions*: i, HC≡CH, acetone, *hν*, 69–72%; ii, NaOMe–MeOH; iii, $LiAlH_4$, 62% **5a** from **3**; iv, *tert*-butyldimethylsilyl chloride (TBSCl), 1*H*-imidazole, dimethylformamide, 99%; v, *m*-chloroperbenzoic acid, CH_2Cl_2, 98%; vi, NaH, AdH, DMSO, 18-crown-6, 114 °C, 28 h, 59%; vii, PhOCSCl, 4-dimethylaminopyridine, MeCN, 18 h, 83%; viii, Bu^n_3SnH, azoisobutyronitrile, heat, dioxane, 30 min, 73%; ix, AcOH–H_2O (4 : 1), 90 °C, 1.5 h, quant.

† Presented at the CATG Meeting, NIH/NIAID, Washington, DC, April 1991 and at the 33rd GECO Conference, Corsica, France, September 1992.

‡ The stereochemistry of the *cis* and *trans* dimethyl 3-cyclobutene-1,2-dicarboxylates was easily assigned by heating them to ~100 °C for 2 h and analysing the known *E*,*E*- and *E*,*Z*-isomers of dimethylhexa-2,4-dienoates (~5.5 : 1) by ^{1}H NMR.



Scheme 2 *Reagents and conditions*: i, AcOH–H_2O (4 : 1), 90 °C, 1.5 h, 96%; ii, PCC–CH_2Cl_2, 75%; iii, (*a*) L-Selectride, tetrahydrofuran (THF), 95% (*b*) AcOH–H_2O, 91%; iv, AcOH–H_2O, 94%



Scheme 3 *Reagents and conditions*: i, MeOH, H_2SO_4, 25 °C, 48 h, 94%; ii, immobilized PLE, acetone, pH 7 buffer, 92%, iii, LDA (2 equiv.), THF, −78 °C; H_3O^+, 95%; iv, $LiAlH_4$; SiO_2, 53% **5a** from **4b**; v, as before

reduced to an easily separable 5 : 1 mixture of the *trans* and *cis* diols **5a,b**, from which the desired *trans* isomer **5a** could be isolated in 62% yield for the two steps from **3**.[6] Protection of this C_2-symmetric diol as the bis-(*tert*-butyldimethylsilyl)ether **6** and epoxidation furnished the epoxide **7** in nearly quantitative yield for the two steps (only one epoxide is possible due to the C_2 symmetry of the bis-ether). Opening of the epoxide was accomplished with high regioselectivity by treating **7** with adenine (AdH) and sodium hydride in dimethyl sulfoxide (DMSO) in the presence of 18-crown-6 at 114 °C for 28 h. This produced a 13 : 1 mixture of the all-*trans* isomer **8a** and a minor byproduct, tentatively assigned the *trans-cis-trans* structure **8b**,§ in 59% yield (Ad = 7-adenyl). Compound **8a** can be isolated free of its isomer by crystallization from dichloromethane–hexane (52% yield from **7**). Not surprisingly, opening of the epoxide *via* path *a* is greatly favoured over that *via* path *b* due to the much larger steric hindrance associated with the latter mode of attack. The stereochemistry of **8a** was tentatively assigned on the basis of the expected favoured approach of attack and the pattern of the coupling constants of the methine protons in the high field ^1H NMR spectrum of **8a** (H_a: δ 4.19, dd, *J* 7.7, 7.2 Hz; H_b: δ 4.10, dd, *J* 8.1, 6.9 Hz).[7] This tentative assignment was confirmed when **8a** was converted into cyclobut-A **1a** as follows. Deoxygenation of the secondary alcohol of **8a** was carried out by a Barton radical process,[8] namely formation of the *O*-phenyl thiocarbonate **9** (83%) and reduction with tri(n-butyl)stannane (73%) to give the bis-silyl ether of cyclobut-A **10** in 61% overall yield for the two-step operation. Final acid-catalysed desilylation furnished the desired antiviral agent, cyclobut-A **1a**, in quantitative yield, thus ending an efficient eight-step synthesis which proceeds in 20% overall yield from **3**. The synthetic material was identical to an authentic sample by ^1H and ^{13}C NMR.

This synthetic approach allowed us to prepare several analogues of cyclobut-A unavailable by other routes. For example, hydrolysis of the silyl ethers of **8a** afforded in 96% yield the triol **11**, a hydroxylated analogue of cyclobut-A (Scheme 2). The epimeric triol **13** could also be easily prepared. Oxidation of **8a** with pyridinium chlorochromate (PCC) in dichloromethane produced in 75% yield the ketone **12** which was then reduced from the less hindered face with L-Selectride to give the *trans-cis-cis* isomer of **8a**. Acidic hydrolysis furnished the desired triol **13**, another hydroxylated analogue of **1a**. Finally removal of the silyl protecting groups from the ketone **12** afforded compound **14**, the keto analogue of cyclobut-A.

We have also completed a simple chiral synthesis of (−)-cyclobut-A (−)-**1a** based on similar chemistry (Scheme 3). Opening of the anhydride **3** with acidic methanol afforded the known *cis*-diester **15** in high yield.[9] This diester contains a plane of symmetry and therefore should be a good candidate for enzymatic enantioselective hydrolysis. Treatment of **15** with pig liver esterase (PLE) at pH 7 gave the desired monoester which was somewhat difficult to separate from the enzyme.[10] However the use of PLE immobilized on a modified azlactone mixed polymer¶ in a pH 7 buffer containing 5% acetone afforded the desired optically active monoester (+)-**4b** in 92% chemical yield with an enantiomeric excess (e.e.) of 86% [determined by ^1H NMR measurements of the diastereoisomeric (*S*)-α-methylbenzylamine salts]. All that remained was to isomerize the correct carbonyl group, which was accomplished by treatment with 2 equiv. of lithium diisopropylamide (LDA) to generate the dianion followed by quenching at −78 °C to give a 3.1 : 1 mixture of the desired *trans* monoester (+)-**4a** and the starting material (+)-**4b**. Direct reduction of the mixture followed by chromatography produced the desired (*S,S*)-diol (+)-**5a** in an overall yield of 53% from (+)-**4b**. The e.e. of this diol was determined to be 81% by examination of the ^1H NMR spectra of the bis-Mosher's esters of both (+)-**5a** and the racemic compound **5a**. The synthesis of optically active (−)-cyclobut-A, (−)-**1a**, was

§ The small amount of this material, and the fact that it could not be obtained pure, did not permit a definite assignment of its structure. Although we favour structure **8b**, we cannot rule out other reasonable alternatives, *e.g.* the corresponding 9-adenyl isomer of **8a**.

¶ Generously supplied by Dr Steve Heilman, 3M, St Paul, MN.

carried out exactly as described for the racemic series in comparable yields.‖

We are currently extending this efficient synthesis to the preparation of other similar cyclobutyl nucleosides, *e.g.* cyclobut-G **1b**, and further analogues in both the racemic and optically active series. The analogues **11**, **13** and **14** are currently being tested for antiviral activity (both CMV and HIV), the results of which will be reported when they are available.

We thank the National Institutes of Health (AI-26692 and GM-47228) for generous financial support, the Swiss National Science Foundation for a postdoctoral fellowship to A. W. S., and Drs G. Bisacchi, J. Bogden and R. Zahler of Bristol-Myers Squibb for an authentic sample of Cyclobut-A (SQ-34990).

Received, 9th November 1992; Com. 2/05977K
