ABSTRACT

Thermolysis of the 3,5-hexadienyl acrylates (a) proceeds via the transition state E in which the connecting chain adopts a boatlike conformation due to a preference for maintaining ester overlap to afford the products b with good diastereoselectivity.

Eleutherobin 1, a novel diterpene isolated from a sea sponge, exhibits potent cytotoxicity against a wide variety of cancer cells (IC50 10–15 nM).\(^1\)

In an approach to the total synthesis of eleutherobin, we postulated that the cyclohexene ring of 1 could possibly be constructed by an intramolecular Diels–Alder reaction of a substituted hexadienyl crotonate as shown in Scheme 1. We hoped to utilize the one stereocenter \(\alpha\) to the oxygen in ester 2 to set the additional three stereocenters required in substructure 3 which could then be converted by reduction and Wittig reaction into compound 4 and then into eleutherobin 1. We first determined that the isopropyl substituent would not undermine the preference of this type of cycloaddition for the cis ring juncture which was shown by Martin et al. for the parent case.\(^2\) Mitsunobu reaction\(^3\) of alcohol 5\(^4\)

with carboxylic acid 6\(^5\) gave ester 7 in good yield. A variety of conditions were examined to optimize the yield and diastereoselectivity of this and the later Diels–Alder reactions. Lewis acids did catalyze the Diels–Alder reaction but also gave a significant amount of undesired side products as did various polar solvents. However, heating triene 7 at 150 °C for 10 days in 1,2-dichlorobenzene gave the endo and exo lactones 8a and 8b in a 5:1 ratio in 79% yield.\(^6\)

Thus, as Martin had found, the reaction is quite sluggish but affords primarily the cis-fused isomer.

We postulated that the intramolecular Diels–Alder reaction of an ester such as 2 might occur with the required diastereoselectivity to provide the relative stereochemistry found in eleutherobin. Of the two possible diastereomeric chairlike endo transition states A and B, the former would be greatly favored over the latter due to the severe steric interaction between the vinylic methyl and the R group in B and thus C should be formed preferentially (Scheme 2).

However, on closer examination of these transition structures using molecular models, we realized that the overlap between the carbonyl and oxygen of the ester group is poor in both transition states A and B. Since such overlap is worth 10–13 kcal/mol,\(^7\) other normally less-favored boatlike transition states which retain this overlap may well be favored since the boat-chair difference is roughly 4.7–6.2 kcal/mol.\(^7\) Thus, one must consider two other diastereomeric endo transition states, E and F (Scheme 3), in which the tether adopts a boatlike conformation in order to allow the ester group to retain coplanarity during the cycloaddition. Of these two transition structures, one would expect E to be greatly favored over F due to a strong steric interaction between the vinylic hydrogen and the axial group 1,4 to it (a flagpole–flagpole interaction).\(^7\) Thus, one would expect compound G to be the major diastereomer formed. It should be pointed out that certain intramolecular Diels–Alder reactions, e.g., those of substituted 1,7,9-decatrien-3-ones, have been shown to proceed predominantly through a boatlike conformation of the connecting chain.\(^8\)

The substrate used to test these mechanistic ideas, 9, was prepared from alcohol 5 by oxidation, addition of methylmagnesium bromide, and Mitsunobu reaction with acid 6. Heating 9 in 1,2-dichlorobenzene at 150 °C for 10 days gave a 76% yield of a 5:1 ratio of the two diastereomeric lactones 10a and 10b. The structures of both 10a and 10b were

---

(6) The structures were determined by a combination of NMR techniques, both NOE experiments and simple coupling data (obtained by double irradiation). In particular, there is an interesting effect on chemical shift due to interaction of the isopropyl methine proton H\(^a\) with the carbonyl group in 8b. This proton appears at quite low field (δ 2.8–3.4, depending on solvent) as a doublet of septets due to this interaction, which is possible only in this half chair-chair trans conformation. For a similar argument in the xestobergsterol class of antihistamines, see: Jung, M. E.; Johnson, T. W. J. Am. Chem. Soc. 1997, 119, 12412.
conclusively shown by proton NMR data, especially NOESY experiments, which showed a strong correlation between the proton α to the lactone oxygen and both ring juncture protons in 10a and with only the proton α to the carbonyl in 10b. Thus, the Diels–Alder reaction presumably proceeds via endo transition state E, namely, with the tether in a boatlike conformation that maximizes ester overlap. It is interesting to note that minor isomer 10b must be formed from the other possible transition state in which the tether adopts a boatlike conformation, namely, the exo transition structure I, which would then give rise to J as the cycloadduct.

The size of the group α to the oxygen is not a significant factor in terms of diastereotopic control. Thus, commercially available aldehyde 11 was converted in several steps (the key enantioselective step being a Sharpless asymmetric dihydroxylation) into the late intermediate 12 for the synthesis of eleutherobin. Cycloaddition occurred on heating 12 in toluene in a sealed tube at 150 °C for 10 days to give in quantitative yield a 5:1 ratio of the two diastereomeric lactones, 13a and 13b, in which again the product formed via transition state E was the major product. The structures were proven by NMR experiments, especially NOESY, which again showed correlation between the proton α to the lactone oxygen and the ring juncture protons.11

The closest analogy to this work in the literature is that of Alexakis who reported that the trans 1,2-disubstituted cyclohexyl analogues 14 (R = H, Me) afforded the analogous products 15 in good yield. However, although they postulated that the reaction proceeded via a similar boatlike conformation of the connecting chain, they ascribed its stability to the presence of the Lewis acid in their case. Thus, we are the first to use the argument of the Lewis acid in their case. Thus, we are the first to use the argument of the Lewis acid in their case. Thus, we are the first to use the argument of the Lewis acid.

In conclusion, we have shown that the thermal intramolecular Diels–Alder cycloaddition of substituted 3,5-hexadienyl acrylates proceeds via a novel transition structure in which the tether adopts a boatlike conformation to maximize overlap of the ester group. The application of this process to the total synthesis of eleutherobin is currently underway in our laboratories.

Supporting Information Available: Proton and carbon NMR data for all the cycloadducts 8ab, 10ab, and 13ab and procedures for their preparation. This material is available free of charge via the Internet at http://pubs.acs.org.

(9) Two other pieces of data in the proton NMR spectra were helpful in assigning structure 10b for the minor isomer, namely, the proton β to the carbonyl is a large dd (J = ~12 Hz) and again the isopropyl methine proton appears at very low field.5

(11) There is a very small amount of another minor isomer (accounting for about 20% of the minor product 13b) which was not isolated in pure form but most likely is the other cis ring juncture compound, C, e.g., that produced from the endo chairlike transition state A.

(13) Mori reported that the analogue having an acetyl group on the distal carbon of the enolate afforded the trans-fused product ii as the only crystalline product isolated in 54% yield. However, it is well-known that activating groups at the distal end of allenes often dominate the stereoccontrol of intramolecular Diels–Alder reactions and therefore these systems are not directly comparable. Mori, K.; Gupta, A. K. Tetrahedron 1985, 41, 5295. The structural assignment of ii indicates that an equilibration of one of the two carbonyl functions must have occurred since the stereochemistry of the alkene is not retained in the Diels–Alder reaction, i.e., either the proton α to the acetyl group or the lactone carbonyl has been epimerized in the product.

(14) After the original submission of this manuscript, we learned of a very similar study by Kurth, et al., who recently presented a poster on this work. Kurth, M. J.; Kim, P.; Olmstead, M. M.; Nantz, M. H. 219th National Meeting of the American Chemical Society, San Francisco, March 26-30, 2000; ORGN 343.
